Ideation Phase
Problem statement

Date	**07 March 2026**
Team ID	**SWTID-2026-8307**
Project Name	**Enforcing Mandatory fields using UI policies and migratting Changes with update sets**
Maximum Marks	**4 Marks**

Problem Statement

In many ServiceNow applications, users sometimes submit forms without filling important fields. When mandatory information such as category, description, or assignment group is missing, it can create issues in data management and incident tracking. Incomplete data may lead to confusion, delays in resolving incidents, and difficulty in generating accurate reports.

Another challenge in ServiceNow development is managing system configuration changes between different environments such as development, testing, and production. When developers make changes like creating UI policies, modifying forms, or updating configurations, these changes must be moved safely to other instances. If changes are migrated manually, there is a higher risk of missing configurations or creating inconsistencies in the system.

Understanding the Problem

The main problem identified in this project is related to **data integrity and configuration management** within the ServiceNow platform. When users interact with forms, they may accidentally skip important fields or provide incomplete information. This can cause problems for support teams who rely on accurate data to manage incidents and requests.

Additionally, developers often work in a development environment where they create or modify system configurations. These changes must later be moved to testing and production environments. Without a proper migration method, it becomes difficult to maintain consistency across the system.

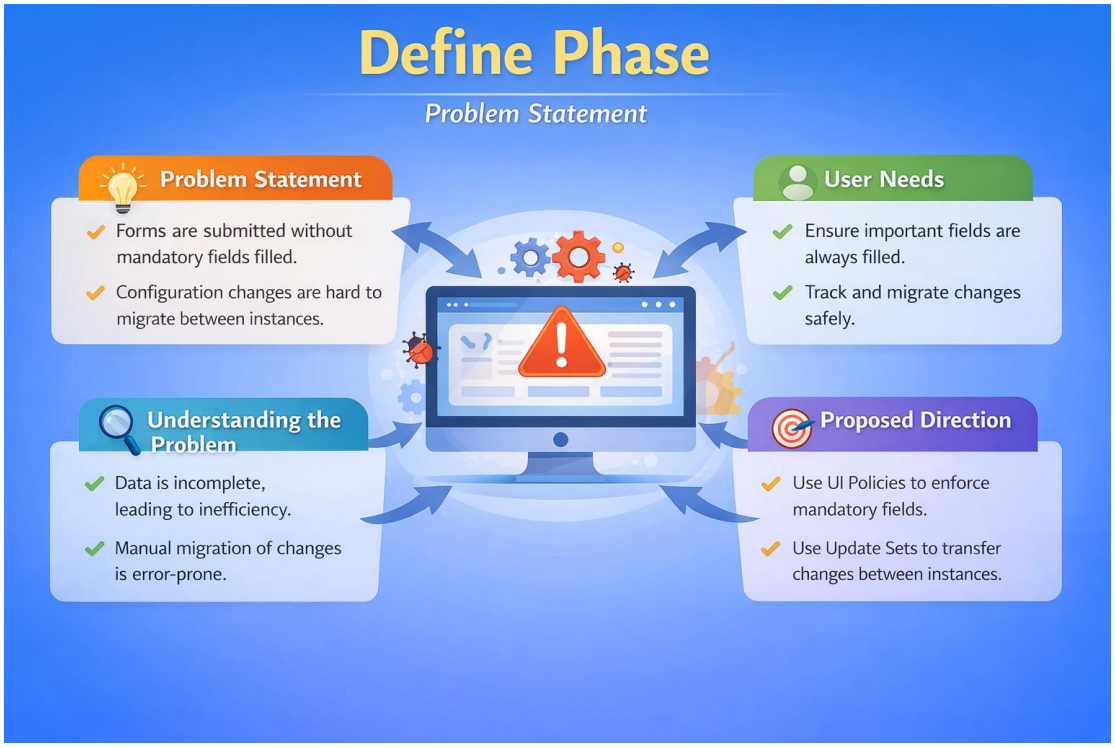
User Needs

The system users and administrators require a solution that ensures:

• Important form fields cannot be left empty
• Data entered into the system is complete and accurate
• Configuration changes can be tracked properly
• Changes can be migrated safely between ServiceNow

Proposed Direction

To solve the identified problems, the project focuses on implementing **UI Policies** to enforce mandatory fields dynamically on forms. UI Policies allow administrators to control field behavior without writing complex scripts.

Additionally, **Update Sets** will be used to capture and migrate configuration changes from one instance to another. This ensures that all changes made during development are properly tracked and deployed to other environments.


By combining UI Policies and Update Sets, the system can maintain better data integrity, improve workflow efficiency, and ensure smooth migration of system configurations.
